Keywords: Metamaterial Topological interface state Hourglass lattice Band gap Spectral element method

ABSTRACT

Topological interface state formation in elastic structures has attracted extensive research interest. However, most previous studies only explored the topological properties of simple structures, such as plain beams and rods. This study explores the feasibility and methodology of producing topological interface states in hourglass lattice sandwich meta-structures. By extending the spectral element method (SEM), a theoretical framework is developed for analyzing such meta-structures. The results obtained by the analytical model agree well with the finite element (FE) simulation results. Based on the analytical model, we maintain the substrate plates and vary the radii of the struts that constitute the hourglass lattice to explore the topological change. The band inversion is identified in the first band gap by inspecting the band edge evolution pattern. The analysis also indicates that the second band gap does not support topological interface states. Subsequently, the vibration modes at band gap edges are examined to confirm the polarization transition. Based on these analyses, a topological sandwich metastructure is designed. An ordinary meta-structure without using the topological design strategy is also constructed. Compared with the ordinary meta-structure, a solitary peak occurs on the transmittance curve of the topological meta-structure in the first band gap. The vibration mode at the solitary peak demonstrates that the transverse motion concentrates at the junction interface, exhibiting the typical energy localization behavior of topological interface states.

1. Introduction

Inspired by topological insulators in condensed matter physics, researchers in other disciplines have extended the topological concepts to the classical physics domain $[1-3]$ $[1-3]$. Elastic metamaterials $[4,5]$ $[4,5]$, in the form of carefully engineered periodic structures, demonstrate extraordinary properties for wave manipulation [\[6\]](#page-15-0). In recent years, elastic metamaterials with topological phases have been widely explored to realize unprecedented topological properties [\[7,8\]](#page-15-0). Unorthodox dynamic phenomena have been observed and realized in topological metamaterials, including interface modes [\[9\],](#page-15-0) polarization transition [\[10\]](#page-15-0), energy localization [\[11\]](#page-15-0), topological protection [\[12\],](#page-15-0) etc.

Fundamentally, the marvelous characteristics of metamaterials can stem from two distinct mechanisms, i.e., Bragg scattering (BS) [\[13\]](#page-15-0) and local resonance (LR) [\[14\].](#page-15-0) The BS mechanism usually generates a wide band gap, but the lattice constant is required to be of the same scale as the wavelength [\[15\].](#page-15-0) In contrast, the LR mechanism is independent of the size of periodic structures, which enables the opening of low-frequency band gaps [\[16\].](#page-15-0) Unfortunately, the LR band gaps are relatively much narrower. The fundamental LR mechanism can be easily understood by referring to the lumped representation [[17,18](#page-15-0)]. In practical systems, such as plates, beam-like resonators can be designed to produce the LR mechanism [[19,20\]](#page-15-0). Besides, such meta-structures share a common feature that multiple lumped mass-spring resonators are embedded into the idealized homogenized lattices [\[21](#page-15-0)–23]. Thus, the complexity of most meta-structures is so high that the fabrication cost may become a hurdle [\[24\].](#page-15-0) Recently, Wen et al. [\[25\]](#page-15-0) harmonized the material properties with geometrical periodicity to enhance the vibration reduction capacity in wide frequency ranges. For creating multiple band gaps, Tian et al. [\[26\]](#page-15-0) merged BS and LR band gaps by introducing

Fig. 1. Schematic of the sandwich meta-structure with hourglass lattices. (a) Isometric view; (b) Top view. Each unit cell is composed of two hourglass lattices, whose corresponding support trusses are of different radii r_1 and r_2 . The length, width, and height of each unit cell are $2l_c$, w_c , and $h_t + 2t_p$, respectively. Here, t_p denotes the thickness of the substrate plate. The length, width, and height of each hourglass lattice are l_b w_b and h_b respectively.

spiral holes in elastic metamaterials. However, most metamaterial structures are designed with multiphase material, and the coupled band gaps are highly related to inclusions [\[27\].](#page-15-0) Due to fabrication barriers and stability risks, these complicated metamaterials have difficulties in practical implementation.

Unlike acoustic and electromagnetic waves, manipulating elastic waves is more difficult because of diverse vibration modes. The discovery of the topological interface state provides a novel waveguiding paradigm [\[3\]](#page-15-0). The emergence of topological interface states can be detected and predicted by mode transition or band inversion [[10,28](#page-15-0)], and different topologies can be characterized by topological invariants such as the Zak phase [\[29\]](#page-15-0). Generally, there are two strategies to realize topological interface states. The first strategy is to break time-reversal symmetry [\[30\].](#page-15-0) According to this strategy, particular components such as gyroscopic units [\[31\]](#page-15-0) and rotational flows [\[32\]](#page-15-0) have to be introduced into the mechanical metamaterials. By mimicking the quantum hall effect, the elastic waves only propagate along a single direction. The second strategy relies on the removal of Dirac degeneracy [\[33\]](#page-15-0). For example, Muhammad et al. [\[34\]](#page-15-0) altered the mode polarization behavior of a combinatorial beam to engender band transition. Zhao et al. [\[28\]](#page-15-0) obtained two topological interface states by attaching mass-spring resonators to a monatomic chain. Recent studies [[35,36\]](#page-15-0) reported that adjusting the local resonators could also yield the Dirac cones. Nevertheless, in those topological metamaterials, the contributions of the local resonators lie in generating the band folding effect. The interface state formation and polarization transition still rely on the phononic crystal-featured host structures [[37,38](#page-15-0)].

Regarding the modeling methods of metamaterials, the widely adopted analytical approaches include the transfer matrix method (TMM) [\[39\],](#page-15-0) the finite element method (FEM) [\[40\],](#page-15-0) the spectral element method (SEM) [\[25\],](#page-15-0) and the plane wave expansion method (PWEM) [\[41\]](#page-15-0). Among these methods, it is intractable for the TMM to model complex structures, so its availability is restricted to one-dimensional systems [\[42\]](#page-15-0). The FEM has the advantage of modeling structures with arbitrarily complex geometries. However, extremely fine meshes are required to ensure accuracy at high frequencies [\[43\]](#page-15-0) due to the utilization of low-order shape functions. Similar to the FEM, the PWEM also demands a sufficient number of wave vectors at each band gap [\[8,44](#page-15-0)]. Unlike the FEM and PWEM, the SEM directly applies the discrete Fourier transforms to derive the exact frequency-domain solution. Therefore, a single spectral element suffices to characterize a uniform structural segment [\[45\]](#page-15-0). Since a significantly reduced amount of meshes is needed, the computational efficiency can be remarkably boosted [\[45](#page-15-0)–47]. Due to its unique merits, the SEM has been applied to evaluate the band gaps of hierarchical structures [\[48\],](#page-15-0) laminate plates [\[49\]](#page-15-0), Kagome lattices [\[50\]](#page-16-0),

etc. However, these investigations are limited to metamaterials modeled by the Levy-type plate theory with two opposite edges under the simply-supported condition.

Although efforts have been devoted to developing and analyzing topological metamaterials, the following questions remain unanswered. (1) Is it possible to realize topological interface states in geometrically complicated composite structures rather than relatively simple and plain structures like beams and plates? (2) How to develop theoretical models of such topological metamaterials using the SEM with high computational efficiency? (3) Regarding the plates involved in the structures, how to extend the SEM to consider more general boundary conditions of universal metamaterial plates with clamped edges?

Motivated by the above research gaps, this study proposes and analyzes a sandwich topological metamaterial with hourglass lattices. The configuration design stems from two facts. On the one hand, sandwich structures are of light weight and high strength, which have been widely used in many areas, such as aerospace and mechanical engineering. Hence, investigating the topological orders in sandwich structures is of significant importance for bringing topological states into practical applications. On the other hand, such sandwich structures can be additively manufactured or assembled by plate and beam elements. By adopting the design method proposed in this paper, the topological interface states can be attained by simply varying the support trusses without modifying the substrate plates and the appearance of the sandwich beam. Moreover, the developed sandwich meta-structure is characterized by a continuous geometry and a single-phase material with no special fabrication requirement. Therefore, from the manufacturing perspective, such topological structures are easy to fabricate.

Since the sandwich metamaterial to be studied in this paper has a complicated structure, it is referred to as the sandwich meta-structure to emphasize its geometric characteristics. Breaking the limitation of the SEM, an extended theoretical framework is put forward to analyze the sandwich meta-structure subjected to general boundary conditions. The study reveals that the topological interface state at low frequency can be stimulated from local resonances through band folding, and the fascinating topological properties can be induced by simply altering the local lattice arrangement without resorting to the active device or the spinorbit interaction.

The rest of the paper is structured as follows. Section 2 presents the sandwich metamaterial with hourglass lattices. The corresponding theoretical model is developed to investigate the topological effect. In Section 3, the dynamic characteristics of the proposed metamaterial are evaluated. [Section 4](#page-11-0) elucidates the topological interface states via band structure and transmittance analyses. Finally, the conclusions of this

Fig. 2. Two-node spectral beam element with complete degrees of freedom. (a) Nodal displacements and rotations; (b) Boundary forces and moments for the bending in the *x*–*y* plane. The degrees of freedom at end nodes are described in the local coordinate system *x*-*y*-*z*, which can be transformed into the global coordinate system X_g -Y_g-Z_g. All boundary conditions are represented in spectral forms, and then they are substituted into the governing equations in the frequency domain.

work are summarized in [Section 5.](#page-14-0)

2. Structural design and theoretical modeling

This section overviews the sandwich meta-structure to be studied in this paper and introduces the SEM modeling procedures.

2.1. Structural overview of the sandwich meta-structure

As depicted in [Fig. 1,](#page-1-0) the sandwich meta-structure is designed with periodic unit cells. Each cell is composed of dual substrate plates and two hourglass lattices. The lattice core consists of eight oblique support trusses with radii of r_1 or r_2 . Different from previous configurations, the radii of the neighboring trusses are alternately varied to enhance the impedance mismatch for producing a wider BS band gap. The structure is characterized by a continuous geometry and a single-phase material with no special fabrication requirement.

From the topology perspective, the sandwich meta-structure is an assembly of the beam and plate elements. Therefore, the dynamic stiffness matrices of the core trusses and the top and bottom plates can be derived independently, then properly assembled together to reflect the dynamic property of the sandwich meta-structure. The combined formulation can not only provide insights into the dynamic behavior of this specific case but also offer a unified theoretical framework for analyzing other similar meta-structures with analogous lattices.

In view of the above merits, this study will first extend the SEM to derive the exact dynamic stiffness of the lattice trusses and substrate plates in the following subsections. On this basis, procedures for the spectral element assembly and boundary condition implementation will be introduced to complete the modeling of the whole structure. Finally, the frequency-domain dynamic response will be predicted and compared with the finite element (FE) results for verification.

2.2. Dynamic stiffness formulation for the hourglass lattice

This subsection focuses on formulating the dynamic stiffness matrix (DSM) of the trusses. Instead of the standard spectral beam element that only simulates transverse deflection, the extended beam model is developed to account for the tensile, torsion, and bending deformations.

A two-node spectral beam element with twelve degrees of freedom, as shown in Fig. 2, is constructed. According to Timoshenko's beam theory, the governing equations of the beam transverse vibration are written as

$$
\begin{cases}\n\kappa GA \left[\frac{\partial^2 v(x,t)}{\partial x^2} - \frac{\partial \theta_z(x,t)}{\partial x} \right] - \rho A \frac{\partial^2 v(x,t)}{\partial t^2} = 0 \\
EI_z \frac{\partial^2 \theta_z(x,t)}{\partial x^2} + \kappa GA \left[\frac{\partial v(x,t)}{\partial x} - \theta_z(x,t) \right] - \rho I_z \frac{\partial^2 \theta_z(x,t)}{\partial t^2} = 0\n\end{cases}
$$
\n(1)

where ρ and κ are the mass density and the shear correction factor [\[51\]](#page-16-0), respectively; *G* and *E* are the Young's modulus and shear modulus, respectively; *A* is the cross-sectional area of the beam; *v* is the transverse displacement along the *y* axis; θ ^z and I ^z denote the rotational angle and the area moment of inertia around the *z*-axis, respectively.

The dynamic responses of ν and θ ^z can be represented in the spectral form [\[52\]](#page-16-0) as below:

$$
\begin{cases}\nv(x,t) = \frac{1}{N} \sum_{n=1}^{N} V_n(x,\omega_n) e^{i\omega_n t} \\
\theta_z(x,t) = \frac{1}{N} \sum_{n=1}^{N} \Theta_{z,n}(x,\omega_n) e^{i\omega_n t}\n\end{cases}
$$
\n(2)

where V_n and $\Theta_{z,n}$ are the spectral amplitudes of v and Θ_z , and ω_n is the *n*th angular frequency. By substituting Eqs. (2) into Eq. (1) , the governing equations are transformed into the frequency domain:

$$
\begin{cases}\n\kappa GA \left(\frac{\partial^2 V}{\partial x^2} - \frac{\partial \Theta_z}{\partial x}\right) + \rho A \omega^2 V = 0 \\
EI_z \frac{\partial^2 \Theta_z}{\partial x^2} + \kappa GA \left(\frac{\partial V}{\partial x} - \Theta_z\right) + \rho I_z \omega^2 \Theta = 0\n\end{cases}
$$
\n(3)

Mathematically, the general solutions of the above differential equations are given by

$$
\begin{cases} V = \alpha_1 e^{-ik_1x} + \alpha_2 e^{-ik_2x} + \alpha_3 e^{-ik_3x} + \alpha_4 e^{-ik_4x} \\ \Theta_z = \beta_1 e^{-ik_1x} + \beta_2 e^{-ik_2x} + \beta_3 e^{-ik_3x} + \beta_4 e^{-ik_4x} \end{cases}
$$
 (4)

where the four roots of the characteristic equation can be obtained as

$$
\begin{cases}\nk_1 = -k_2 = \frac{k_F}{\sqrt{2}} \sqrt{\eta_1 k_F^2 + \sqrt{\eta_1^2 k_F^4 + 4(1 - \eta_2 k_G^4)}} \\
k_3 = -k_4 = \frac{k_F}{\sqrt{2}} \sqrt{\eta_1 k_F^2 - \sqrt{\eta_1^2 k_F^4 + 4(1 - \eta_2 k_G^4)}}.\n\end{cases}
$$
\n(5)

with the intermediate variables defined by

$$
k_F = \sqrt{\omega} \left(\frac{\rho A}{EI_z}\right)^{\frac{1}{4}}, k_G = \sqrt{\omega} \left(\frac{\rho A}{\kappa GA}\right)^{\frac{1}{4}}, \eta_1 = \frac{I_z}{A} + \frac{EI_z}{\kappa GA}, \eta_2 = \frac{I_z}{A}.
$$
 (6)

Besides, the corresponding coefficient β *j* ($j = 1, 2, 3, 4$) is expressed as

$$
\beta_j = -i(k_j - k_G^4 / k_j). \tag{7}
$$

Following the procedure of the SEM, the boundary conditions are further imposed:

$$
\begin{cases} V_1 = V|_{x=0}, V_2 = V|_{x=L}, \Theta_{z1} = \Theta_z|_{x=0}, \Theta_{z2} = \Theta_z|_{x=L} \\ F_{y1} = F_y|_{x=0}, F_{y2} = F_y|_{x=L}, M_{z1} = M_z|_{x=0}, M_{z2} = M_z|_{x=L} \end{cases}
$$
\n(8)

where *L* denotes the beam length. The internal transverse shear force and bending moment are determined by

$$
F_{y} = \kappa GA \left(\frac{\partial V}{\partial x} - \Theta_{z}\right), M_{z} = EL_{z} \frac{\partial \Theta_{z}}{\partial x}.
$$
\n(9)

Hence, the vectors of nodal displacements and forces for the bending in

Fig. 3. Rectangular thin plate element in the local coordinate. The length, width, and thickness of the plate are 2*a*, 2*b*, and *h*, respectively. The amplitudes of transverse displacement, transverse rotations, shear forces, and bending moments are *W, Θx, Θy, Vx, Vy, Mx*, and *My*, respectively.

the *x*-*y* plane satisfy the following relationship:

$$
\mathbf{S}_{\nu}(\omega)\mathbf{d}_{\nu} = \mathbf{F}_{\nu}, \mathbf{d}_{\nu} = [V_1, \Theta_{z1}, V_2, \Theta_{z2}]^T, \mathbf{F}_{\nu} = [F_{y1}, M_{z1}, F_{y2}, M_{z2}]^T.
$$
 (10)

where the DSM S_v can be further expanded as

$$
\mathbf{S}_{\nu}(\omega) = \mathbf{R} \mathbf{H}_{\nu}^{-1},\tag{11}
$$

and the matrices **R** and H_v are given by

where θ_x is the rotational angle around the *x*-axis. We can also map the nodal displacements to the corresponding forces in the frequency domain as below:

$$
\mathbf{S}_{\theta}(\omega)\mathbf{d}_{\theta} = \mathbf{F}_{\theta}, \mathbf{d}_{\theta} = [\mathbf{\Theta}_{x1}, \mathbf{\Theta}_{x2}]^{T}, \mathbf{F}_{\theta} = [M_{x1}, M_{x2}]^{T},
$$
\n(18)

where the DSM **S***θ* is deduced as

$$
\begin{cases}\n\mathbf{R} = \begin{bmatrix}\n-\kappa GA(-ik_1 - \beta_1) & -\kappa GA(-ik_2 - \beta_2) & -\kappa GA(-ik_3 - \beta_3) & -\kappa GA(-ik_4 - \beta_4) \\
iEL_i\beta_1k_1 & iEL_i\beta_2k_2 & iEL_i\beta_3k_3 & iEL_i\beta_4k_4 \\
\kappa GA(-ik_1 - \beta_1)e^{-ik_1L} & \kappa GA(-ik_2 - \beta_2)e^{-ik_2L} & \kappa GA(-ik_3 - \beta_3)e^{-ik_3L} & \kappa GA(-ik_4 - \beta_4)e^{-ik_4L} \\
-iEL_i\beta_1k_1e^{-ik_1L} & -iEL_i\beta_2k_2e^{-ik_2L} & -iEL_i\beta_3k_3e^{-ik_3L} & -iEL_i\beta_4k_4e^{-ik_4L}\n\end{bmatrix}\n\end{cases}
$$
\n
$$
\mathbf{H}_v = \begin{bmatrix}\n1 & 1 & 1 & 1 \\
\beta_1 & \beta_2 & \beta_3 & \beta_4 \\
e^{-ik_1L} & e^{-ik_2L} & e^{-ik_3L} & e^{-ik_4L}\n\end{bmatrix}
$$
\n(12)

Considering the symmetry of the circular section, the DSM S_w for the bending in the *x-z* plane is identical to **S***v*. Thus, we can directly obtain

$$
\mathbf{S}_{w}(\omega)\mathbf{d}_{w} = \mathbf{F}_{w}, \mathbf{d}_{w} = [W_{1}, \Theta_{y1}, W_{2}, \Theta_{y2}]^{T}, \mathbf{F}_{w} = [F_{z1}, M_{y1}, F_{z2}, M_{y2}]^{T}.
$$
 (13)

As to the tensile of the beam, the motion is governed by

 $\beta_1 e^{-ik_1L}$ $\beta_2 e^{-ik_2L}$ $\beta_3 e^{-ik_3L}$ $\beta_4 e^{-ik_4L}$

$$
\rho \frac{\partial^2 u(x,t)}{\partial t^2} - E \frac{\partial^2 u(x,t)}{\partial x^2} = 0
$$
\n(14)

where *u* is the axial displacement. Similarly, the corresponding nodal forces and displacements take the below form

$$
\mathbf{S}_{u}(\omega)\mathbf{d}_{u} = \mathbf{F}_{u}, \mathbf{d}_{u} = [U_{1}, U_{2}]^{T}, \mathbf{F}_{u} = [F_{x1}, F_{x2}]^{T}.
$$
\n(15)

In detail, the DSM S_u is derived as

$$
\mathbf{S}_{u}(\omega) = \frac{k_{u}EA}{\sin(k_{u}L)} \begin{bmatrix} \cos(k_{u}L) & -1\\ -1 & \cos(k_{u}L) \end{bmatrix}, k_{u} = \omega \sqrt{\frac{\rho}{E}}.
$$
 (16)

For the torsional motion of the beam, the governing equation is written as

$$
\rho \frac{\partial^2 \theta_x(x,t)}{\partial t^2} - G \frac{\partial^2 \theta_x(x,t)}{\partial x^2} = 0
$$
\n(17)

$$
\mathbf{S}_{\theta}(\omega) = \frac{GI_{\rho}}{L} \frac{k_{\theta}L}{\sin(k_{\theta}L)} \begin{bmatrix} \cos(k_{\theta}L) & -1\\ -1 & \cos(k_{\theta}L) \end{bmatrix}, k_{\theta} = \omega \sqrt{\frac{\rho}{G}},
$$
(19)

where I_{ρ} denotes the polar inertia moment of the cross-sectional area.

By assembling Eqs. (11) , (13) , (15) and (18) , the complete DSM S_b of the beam, including the consideration of the tensile, bending, and torsion deformations, is expressed as

$$
\mathbf{S}_b(\omega)\mathbf{d}_b = \mathbf{F}_b. \tag{20}
$$

In fact, S_b is the combination of S_u , S_v , S_w , and S_θ . The nodal displacements and forces are

$$
\begin{cases} \mathbf{d}_{b} = \begin{bmatrix} U_{1}, V_{1}, W_{1}, \Theta_{x1}, \Theta_{y1}, \Theta_{z1}, U_{2}, V_{2}, W_{2}, \Theta_{x2}, \Theta_{y2}, \Theta_{z2} \end{bmatrix}^{T}, \\ \mathbf{F}_{b} = \begin{bmatrix} F_{x1}, F_{y1}, F_{z1}, M_{x1}, M_{y1}, M_{z1}, F_{x2}, F_{y2}, F_{z2}, M_{x2}, M_{y2}, M_{z2} \end{bmatrix}^{T} . \end{cases}
$$
(21)

2.3. Dynamic stiffness formulation for the substrate plate

This section presents the formulation of the DSM of the substrate plate. Compared with Levy's plate theory used in [\[53\],](#page-16-0) it is more challenging to derive the DSM for the plate element with generalized boundary conditions. Moreover, since plates adopt line nodes, the transformation from line nodes to point nodes is required to make the DSM of the substrate plate compatible with the DSM of the hourglass

Fig. 4. Boundary conditions of the plate element. (a): Definition of the boundary condition applied on the entire plate Ω, (b): Definition of the boundary condition applied on boundaries B*a* and B*b*.

lattice.

 $\overline{ }$

Since the thickness of the substrate plate is much smaller than its width and length, the Kirchhoff thin plate theory is employed to derive the dynamic stiffness formulation. As shown in [Fig. 3](#page-3-0), the governing equation in the frequency domain is expressed as

$$
D\left(\frac{\partial^4 W}{\partial x^4} + 2\frac{\partial^4 W}{\partial x^2 \partial y^2} + \frac{\partial^4 W}{\partial y^4}\right) - \rho h \omega^2 W = 0,
$$
\n(22)

where *W* stands for the amplitude of the transverse vibration; $D = Eh³/$ $[12(1-\mu^2)]$ is the bending stiffness that is associated with the Poisson's ratio *μ* and the thickness *h* of the plate; $ω$ is the angular frequency; $ρ$ is the mass density of the plate. Moreover, the amplitudes of the transverse rotations (Θ_x and Θ_y), shear forces (V_x and V_y), and bending moments $(M_x \text{ and } M_y)$ are expressed as

$$
\begin{cases}\n\Theta_x = \frac{\partial W}{\partial x}, M_x = -D\left(\frac{\partial^2 W}{\partial x^2} + \mu \frac{\partial^2 W}{\partial y^2}\right), V_x = -D\left(\frac{\partial^3 W}{\partial x^3} + (2 - \mu) \frac{\partial^3 W}{\partial x \partial y^2}\right) \\
\Theta_y = \frac{\partial W}{\partial y}, M_y = -D\left(\frac{\partial^2 W}{\partial y^2} + \mu \frac{\partial^2 W}{\partial x^2}\right), V_y = -D\left(\frac{\partial^3 W}{\partial y^3} + (2 - \mu) \frac{\partial^3 W}{\partial y \partial x^2}\right).\n\end{cases}
$$
\n(23)

According to [\[54\]](#page-16-0), the combination of modified Fourier basis functions provides an accurate and robust description of the plate motion for arbitrary boundary conditions. On this basis, the variable separation technique is applied to obtain the general solution of *W*, which is formulated as

$$
\alpha_{km} = \begin{cases} m\pi x/ak = 0\\ (m+0.5)\pi x/ak = 1 \end{cases}, \beta_{jn} = \begin{cases} n\pi y/bk = 0\\ (n+0.5)\pi y/bk = 1 \end{cases}
$$
 (26)

The wave numbers *pkm*1, *pkm*2, *qjn*1, and *qjn*2 can be further determined as

$$
\begin{cases}\np_{km1} = \sqrt{\alpha_{km}^2 - \sqrt{\rho h \omega^2 / D}}, p_{km2} = \sqrt{\alpha_{km}^2 + \sqrt{\rho h \omega^2 / D}} \\
q_{jn1} = \sqrt{\beta_{jn}^2 - \sqrt{\rho h \omega^2 / D}}, p_{jn2} = \sqrt{\beta_{jn}^2 + \sqrt{\rho h \omega^2 / D}}\n\end{cases} (27)
$$

Given the symmetry and anti-symmetry of the basic functions [\[55\],](#page-16-0) Eq. (25) can be further divided into four components:

$$
W(x, y) = \sum_{k, j \in \{0, 1\}} W^{kj}(x, y) = W^{00} + W^{01} + W^{10} + W^{11},
$$
\n(28)

where the superscripts k and j correspond to the x and y directions, respectively; *k* and *j* take the values of '0' and '1'; '0' indicates the symmetric component, and '1' denotes the antisymmetric component. To be more specific, the four components are expressed as:

$$
W^{kj}(x, y) = \sum_{m \in M} \left[A_{km1} H_j(p_{km1}y) + A_{km2} H_j(p_{km2}y) \right] T_k(\alpha_{km}x) + \sum_{n \in N} \left[B_{jn1} H_k(q_{jn1}x) + B_{jn2} H_j(q_{jn2}x) \right] T_j(\beta_{jn}y) \qquad (29)
$$

where A_{km1} , A_{km2} , B_{in1} , and B_{in2} are undetermined constants, and *H* represents the hyperbolic functions:

$$
W(x, y) = \sum_{k \in \{0, 1\}, m \in N} T_k(\alpha_{km} x) [C_{km1} \cosh(p_{km1} y) + C_{km2} \cosh(p_{km2} y) + C_{km3} \sinh(p_{km1} y) + C_{km4} \sinh(p_{km2} y)] +
$$

$$
\sum_{j \in \{0, 1\}, n \in N} T_k(\beta_{jn} y) [C_{jn1} \cosh(q_{jn1} x) + C_{jn2} \cosh(q_{jn2} x) + C_{jn3} \sinh(q_{jn1} x) + C_{jn4} \sinh(q_{jn2} x)]
$$
\n(24)

where *Ckm*1–*Ckm*4 and *Cjn*1–*Cjn*4 are unknown coefficients, and *T* denotes the trigonometric functions as below:

$$
T_k(\alpha_{km}x) = \begin{cases} \cos(m\pi x/a)k = 0\\ \sin((m+0.5)\pi x/a)k = 1\\ \cos(n\pi y/b)k = 0 \end{cases}
$$

=
$$
\begin{cases} \cos(n\pi y/b)k = 0\\ \sin((n+0.5)\pi y/b)k = 1 \end{cases}
$$
 (25)

$$
H_j(p_{ikm}y) = \begin{cases} \cosh(p_{ikm}y)k = 0 \\ \sinh(p_{ikm}y)k = 1 \end{cases}, H_k(q_{ijn}x) = \begin{cases} \cosh(q_{ijn}x)j = 0 \\ \sinh(q_{ijn}x)j = 1 \end{cases}.
$$
 (30)

Through the decomposition, the following relation can be deduced from the symmetric and antisymmetric properties:

$$
\begin{bmatrix}\nW(a,y) \\
\Theta_x(a,y) \\
W(x,b) \\
\Theta_y(x,b) \\
W(-a,y) \\
W(-a,y) \\
\Theta_y(x,-b)\n\end{bmatrix} = \begin{bmatrix}\nW_0^{00} + W_0^{01} + W_0^{10} + W_0^{11} \\
\Theta_a^{00} + \Theta_a^{01} + \Theta_b^{10} + \Theta_b^{11} \\
\Theta_b^{00} + \Theta_b^{01} + \Theta_b^{10} + \Theta_b^{11} \\
W_0^{00} + W_0^{01} - W_a^{10} - W_a^{11} \\
W(x,-b) \\
\Theta_y(x,-b)\n\end{bmatrix}, \begin{bmatrix}\nV_x(a,y) \\
M_x(a,y) \\
W_y(x,b) \\
W_x(a,y) \\
W_x(a,y) \\
W_y(a,y) \\
\Theta_b^{00} + \Theta_b^{01} + \Theta_b^{10} + \Theta_b^{11} \\
\Theta_b^{00} - \Theta_b^{01} + \Theta_b^{10} + \Theta_b^{11} \\
W_y(a,y) \\
\Theta_y(x,-b)\n\end{bmatrix}, \begin{bmatrix}\nV_x(a,y) \\
M_x(a,y) \\
V_y(x,b) \\
M_y(x,b) \\
\Theta_y(x,b)\n\end{bmatrix}
$$
\n
$$
= \begin{bmatrix}\nV_a^{00} + W_b^{01} + W_b^{10} + W_b^{11} \\
W_b^{00} + W_b^{01} + W_b^{10} + W_b^{11} \\
M_b^{00} + M_a^{01} + M_a^{10} + M_a^{11} \\
W_b^{00} + W_b^{01} + W_b^{10} + W_b^{11} \\
W_b^{00} + W_b^{01} + W_b^{10} + W_b^{11} \\
W_b^{00} + W_b^{01} + W_b^{10} - W_a^{11} \\
\Theta_b^{00} + W_b^{01} + W_b^{10} + W_b^{11} \\
\Theta_b^{00} + W_b^{01} + W_b^{10} + W_b^{11} \\
\Theta_y(a,y) = \begin{bmatrix}\nV_x(a,y) \\
M_x(a,y) \\
-N_y(a,y) \\
\Theta_y(a,y) \\
\Theta_x(a,y) \\
\Theta_y(a,y) \\
\Theta_y(b,y) \\
\Theta_y(b,y) \\
\Theta_y(b,y) \\
\Theta_y(b,y
$$

As indicated above, the general solution of *W* in the entire region $\Omega = [-a, a] \times [-b, b]$ can be represented by the four components $W^{kj}(x, y)$ in the quarter region $\Omega_1=[0, a] \times [0, b]$ to reduce the computational complexity.

After expanding the solution of the governing equation into the trigonometric series, we will impose the boundary conditions to determine the unknown coefficients that exist in the general solution. Likewise, the boundary displacements and forces are also decomposed into four components defined in $\Omega_1 = [0, a] \times [0, b]$. As depicted in [Fig. 4,](#page-4-0) the boundary conditions are expressed as

$$
\begin{bmatrix}\nW_{a}^{kj} \\
W_{b}^{kj} \\
\Theta_{b}^{kj} \\
\Theta_{b}^{kj}\n\end{bmatrix} = \begin{bmatrix}\nW_{b}^{kj}\Big|_{x=a} \\
W_{b}^{kj}\Big|_{y=b} \\
W_{b}^{kj}\Big|_{y=b} \\
\Theta_{b}^{kj}\Big|_{y=b} \\
\Theta_{
$$

where $\zeta_{st} = 2$ if and only if both *s* and *t* are 0; otherwise, $\zeta_{st} = 1$. By substituting Eqs. (32) into [Eq. \(28\),](#page-4-0) all unknown coefficients *Akm*1, A_{km2} , B_{in1} and B_{in2} in the general solution can be solved as

$$
A_{km1} = \frac{V_{bm} - \Theta_{bm} \left(\nu \alpha_{km}^2 - p_{km1}^2\right)}{(p_{km2}^2 - p_{km1}^2)H_k^*(p_{km2}b)\sqrt{\zeta_{km}a}}, A_{km2} = -\frac{V_{bm} - \Theta_{bm} \left(\nu \alpha_{km}^2 - p_{km2}^2\right)}{(p_{km2}^2 - p_{km1}^2)H_k^*(p_{km1}b)\sqrt{\zeta_{km}a}},
$$

\n
$$
B_{jn1} = \frac{V_{am} - \Theta_{am} \left(\nu \beta_{jn}^2 - q_{jn1}^2\right)}{\left(q_{jn2}^2 - q_{jn1}^2\right)H_j^*(q_{jn1}a)\sqrt{\zeta_{jn}b}}, B_{jn2} = -\frac{V_{am} - \Theta_{am} \left(\nu \beta_{jn}^2 - q_{jn2}^2\right)}{\left(q_{jn2}^2 - q_{jn1}^2\right)H_j^*(q_{jn2}a)\sqrt{\zeta_{jn}b}}
$$
\n(33)

where the introduced differential is defined as

$$
H_k^*(p\xi) = \frac{dH_k(p\xi)}{d\xi}.
$$
\n(34)

Subsequently, combining Eqs. (31) and (33) , we can obtain four algebraic equations associated with all the Fourier coefficients, which are written into a concise form as [\[54\]](#page-16-0)

$$
\begin{bmatrix} W^{kj} \\ M^{kj} \end{bmatrix} = \begin{bmatrix} C_{W\Theta}^{kj} & C_{WV}^{kj} \\ C_{M\Theta}^{kj} & C_{MV}^{kj} \end{bmatrix} \begin{bmatrix} \Theta^{kj} \\ V^{kj} \end{bmatrix}.
$$
 (35)

The vectors \mathbf{W}^{kj} , \mathbf{M}^{kj} , Θ^{kj} and \mathbf{V}^{kj} are expressed as

$$
\begin{cases}\n\mathbf{W}^{kj} = \left[\left(\mathbf{W}_a^{kj}\right)^T, \left(\mathbf{W}_b^{kj}\right)^T\right]^T, \mathbf{M}^{kj} = \left[\left(\mathbf{M}_a^{kj}\right)^T, \left(\mathbf{M}_b^{kj}\right)^T\right]^T \\
\mathbf{\Theta}^{kj} = \left[\left(\mathbf{\Theta}_a^{kj}\right)^T, \left(\mathbf{\Theta}_b^{kj}\right)^T\right]^T, \mathbf{V}^{kj} = \left[\left(\mathbf{V}_a^{kj}\right)^T, \left(\mathbf{V}_b^{kj}\right)^T\right]^T\n\end{cases} (36)
$$

The detailed coefficient matrices are given in Appendix A. Based on the above formulation, we can recast the relationship between the forces and displacement for line nodes as

$$
\begin{bmatrix} V^{kj} \\ M^{kj} \end{bmatrix} = \begin{bmatrix} (C_{WV}^{kj})^{-1} & -(C_{WV}^{kj})^{-1} C_{W\Theta}^{kj} \\ C_{MV}^{kj} (C_{WV}^{kj})^{-1} & C_{M\Theta}^{kj} - C_{MV}^{kj} (C_{WV}^{kj})^{-1} C_{W\Theta}^{kj} \end{bmatrix} \begin{bmatrix} W^{kj} \\ \Theta^{kj} \end{bmatrix}.
$$
 (37)

The DSM for the plate element with line nodes has been obtained. The next step is constructing the force-displacement relationship with point nodes to enable the integration with the DSM of the hourglass lattices later on. To this end, $(N + 1 - k)$ equally-spaced interpolation points are chosen in [0, *a*] along the *x* direction:

$$
\begin{cases} \text{if } k = 0, x_0 = 0, x_1 = a/N, x_2 = 2a/N, \dots, x_N = a \\ \text{if } k = 1, x_1 = a/N, x_2 = 2a/N, \dots, x_N = a \end{cases}
$$
(38)

Table 1

Geometric parameters of the sandwich meta-structure with hourglass lattices.

Structure parameters	Design value (mm)
Plate length l_c	100
Plate width w_c	50
Plate thickness t_n	4
Height of cell h_c	46
Radius of the first lattice r_1	1.5
Radius of the second lattice r_2	2.5

Table 2

Material - structural steel parameters.

Material parameters	Nominal value
Mass density ρ	7850 kg/ m^3
Young's modulus E	200×10^{9} N/m ²
Poisson's ratio μ	0.3
Loss factor n	0.008

Likewise, the segment [0, *b*] in the *y* direction is also characterized by $(N + 1 - j)$ point nodes. The corresponding components of the boundary displacement and force are expressed as

$$
\begin{cases}\nW_a^{kj}(y) = \sum_{s=1}^{N+1-j} W_{as,p}^{kj} T_j(\beta_{js} y), W_b^{kj}(x) = \sum_{s=1}^{N+1-j} W_{bs,p}^{kj} T_k(\alpha_{ks} x) \\
\Theta_a^{kj}(y) = \sum_{s=1}^{N+1-j} \Theta_{as,p}^{kj} T_j(\beta_{js} y), \Theta_b^{kj}(x) = \sum_{s=1}^{N+1-j} \Theta_{bs,p}^{kj} T_k(\alpha_{ks} x) \\
V_a^{kj}(y) = \sum_{s=1}^{N+1-j} V_{as,p}^{kj} T_j(\beta_{js} y), V_b^{kj}(x) = \sum_{s=1}^{N+1-j} V_{bs,p}^{kj} T_k(\alpha_{ks} x) \\
M_a^{kj}(y) = \sum_{s=1}^{N+1-j} M_{as,p}^{kj} T_j(\beta_{js} y), M_b^{kj}(x) = \sum_{s=1}^{N+1-j} M_{bs,p}^{kj} T_k(\alpha_{ks} x)\n\end{cases}
$$
\n(40)

By applying the discrete Fourier transform [\[56\]](#page-16-0), the coefficients of

$$
\begin{cases}\n\boldsymbol{d}_{p} = \left[\left(\boldsymbol{W}_{p}^{kj}\right)^{T}, \left(\boldsymbol{\Theta}_{p}^{kj}\right)^{T}\right]^{T} = \left[\left\{W_{a}^{kj}(y_{s})\right\} \quad \left\{W_{b}^{kj}(x_{t})\right\} \quad \left\{\boldsymbol{\Theta}_{a}^{kj}(y_{s})\right\} \quad \left\{\boldsymbol{\Theta}_{b}^{kj}(x_{t})\right\}\right]^{T} \quad s = j, j + 1, \cdots, N \\
f_{p} = \left[\left(\boldsymbol{V}_{p}^{kj}\right)^{T}, \left(\boldsymbol{M}_{p}^{kj}\right)^{T}\right]^{T} = \left[\left\{V_{a}^{kj}(y_{s})\right\} \quad \left\{W_{b}^{kj}(x_{t})\right\} \quad \left\{M_{a}^{kj}(y_{s})\right\} \quad \left\{M_{b}^{kj}(x_{t})\right\}\right]^{T} \quad t = k, k + 1, \cdots, N\n\end{cases} \tag{39}
$$

The interpolation trigonometric polynomials with respect to the coordinates *x* and *y*, i.e., T_k (α_{km} *x*) and T_j (β_{jn} *y*), can be constructed from the data of given points. Thus, the boundary functions are equivalently expressed as

Eq. (40) are determined from the given values at specific point nodes, which are formulated as

$$
\begin{cases}\nW_{as,p}^{kj} = \sum_{t=j}^{N} F_{as}^{jw} W_{a}^{kj}(y_{n}), W_{bs,p}^{kj} = \sum_{t=j}^{N} F_{bs}^{kw} W_{b}^{kj}(x_{m}), \Theta_{as,p}^{kj} = \sum_{t=j}^{N} F_{as}^{j\theta} \Theta_{a}^{kj}(y_{n}), \Theta_{bs,p}^{kj} = \sum_{t=j}^{N} F_{bs}^{k\theta} \Theta_{b}^{kj}(x_{m}), \\
V_{as,p}^{kj} = \sum_{t=j}^{N} F_{as}^{jw} V_{a}^{kj}(y_{n}), V_{bs,p}^{kj} = \sum_{t=j}^{N} F_{bs}^{kv} V_{b}^{kj}(x_{m}), M_{as,p}^{kj} = \sum_{t=j}^{N} F_{as}^{jm} M_{a}^{kj}(y_{n}), M_{bs,p}^{kj} = \sum_{t=j}^{N} F_{bs}^{km} M_{b}^{kj}(x_{m}).\n\end{cases} (41)
$$

According to Eqs. (40) and (41), the mapping from the Fourier coefficient vectors of point nodes to the displacement component can be constructed as

Fig. 5. Comparison of the transmittances of an example hourglass lattice meta-structure calculated by SEM and FEM. Two primary vibration attenuation valleys appear on the transmittance response over the frequency ranges of 907–1194 Hz and 1735–2240 Hz, respectively.

 \overline{a} $\overline{}$ \overline{a} \overline{a}

$$
\begin{aligned}\n\left[\left(\mathbf{W}^{kj}\right)^{T},\left(\mathbf{\Theta}^{kj}\right)^{T}\right]^{T} &= \mathbf{F}_{dp}^{kj} \left[\left(\mathbf{W}_{p}^{kj}\right)^{T},\left(\mathbf{\Theta}_{p}^{kj}\right)^{T}\right]^{T},\left[\left(\mathbf{V}^{kj}\right)^{T},\left(\mathbf{M}^{kj}\right)^{T}\right]^{T} \\
&= \mathbf{F}_{p}^{kj} \left[\left(\mathbf{V}_{p}^{kj}\right)^{T},\left(\mathbf{M}_{p}^{kj}\right)^{T}\right]^{T}.\n\end{aligned} \tag{42}
$$

Due to the symmetric and antisymmetric properties, the set of boundary displacements and forces evaluated at the nodal points satisfy the relationship:

As a consequence, substituting Eqs. (40) and (43) into Eq. (44) yields

$$
\begin{bmatrix} V_p \\ M_p \end{bmatrix} = \mathbf{D}_p \begin{bmatrix} W_p \\ \mathbf{\Theta}_p \end{bmatrix} . \tag{46}
$$

where the DSM D_p correlates the boundary forces and displacements evaluated at point nodes. Finally, similar to the FEM, the global DSM for

 \perp \mathbf{I} \perp \perp \mathbf{I} \perp \mathbf{I} \perp \mathbf{I} \perp \perp $\mathsf I$ \perp $\mathsf I$ \perp $\mathsf I$ \perp \perp $\frac{1}{2}$ $W_a^{kj}(y_n)$ $\Theta_a^{kj}(y_n)$ $W_b^{kj}(x_n)$ $\Theta_b^{kj}(x_n)$ $M_a^{kj}(y_n)$ $V_a^{kj}(y_n)$ $M_b^{kj}(x_n)$ $V_b^{kj}(x_n)$ $\frac{1}{2}$ $\mathsf I$ $\overline{1}$ $\overline{1}$ $\mathsf I$ $\overline{1}$ $\mathsf I$ $\overline{1}$ $\mathsf I$ $\overline{1}$ $\overline{1}$ $\mathsf I$ $\overline{1}$ $\mathsf I$ $\overline{1}$ $\mathsf I$ $\overline{1}$ $\overline{1}$ $\frac{1}{2}$ $=\frac{1}{4}$ \overline{a} $\overline{1}$ $\mathsf I$ \perp \perp \mathbf{I} \perp $\begin{cases}\nM_x(a, y_n) + (-1)^i M_x(a, -y_n) + (-1)^k M_x(-a, y_n) + (-1)^{k+j} M_x(-a, -y_n) \\
V_x(a, y_n) + (-1)^j V_x(a, -y_n) - (-1)^k V_x(-a, y_n) - (-1)^{k+j} V_x(-a, -y_n) \\
M(x, b) + (-1)^k M(-x, b) + (-1)^j M(x, -b) + (-1)^{k+j} M(-x, -b)\n\end{cases}$ $W(a, y_n) + (-1)^j W(a, -y_n) + (-1)^k W(-a, y_n) + (-1)^{k+j} W(-a, -y_n)$ $\Theta_{y}(a, y_n) + (-1)^{j} \Theta_{y}(a, -y_n) - (-1)^{k} \Theta_{y}(-a, y_n) - (-1)^{k+j} \Theta_{y}(-a, -y_n)$ $W(x_n, b) + (-1)^k W(-x_n, b) + (-1)^j W(x_n, -b) + (-1)^{k+j} W(-x_n, -b)$ $\Theta_x(x_n, b) + (-1)^k \Theta_x(-x_n, b) - (-1)^j \Theta_x(x_n, -b) - (-1)^{k+j} \Theta_x(-x_n, -b)$ $M_x(a,y_n) + (-1)^j M_x(a,-y_n) + (-1)^k M_x(-a,y_n) + (-1)^{k+j} M_x(-a,-y_n)$ $M_y(x_n, b) + (-1)^k M_y(-x_n, b) + (-1)^j M_y(x_n, -b) + (-1)^{k+j} M_y(-x_n, -b)$ $V_y(x_n, b) + (-1)^k V_y(-x_n, b) - (-1)^j V_y(x_n, -b) - (-1)^{k+j} V_y(-x_n, -b)$

Hence, the following linear equations can be constructed with the mapping matrices R_{dp}^{kj} and R_{fp}^{kj} [\[57\]](#page-16-0):

$$
\begin{bmatrix} W_p^{kj} \\ \boldsymbol{\Theta}_p^{kj} \end{bmatrix} = \boldsymbol{R}_{dp}^{kj} \begin{bmatrix} W_p \\ \boldsymbol{\Theta}_p \end{bmatrix}, \begin{bmatrix} V_p^{kj} \\ N_p^{kj} \end{bmatrix} = \boldsymbol{R}_{jp}^{kj} \begin{bmatrix} V_p \\ M_p \end{bmatrix},
$$
\n(44)

where the vectors are introduced as

the whole periodic plate structure can be constructed by assembling the individual DSM.

2.4. Dynamic response of the meta-structure

 \overline{a} \overline{a} \perp \perp \perp \perp \perp \perp \perp \perp \perp $\overline{1}$

By using the DSM, the governing equation can be expressed as:

$$
\mathbf{W}_p = [W(a, y_0), W(-a, y_0), W(a, -y_0), W(-a, -y_0), \cdots, W(x_N, b), W(x_N, -b), W(-x_N, b), W(-x_N, -b)]^T
$$

\n
$$
\mathbf{\Theta}_p = [\Theta_x(x_0, b), \Theta_x(x_0, -b), \Theta_x(-x_0, b), \Theta_x(-x_0, -b), \cdots, \Theta_y(-a, y_N), \Theta_y(a, -y_N), \Theta_y(-a, -y_N)]^T
$$
\n(45)

. (43)

Fig. 7. Eigenmode shapes of the modes labeled in [Fig. 6](#page-7-0): (a) Mode A at the lower bound of the first band gap; (b) Mode B at the upper bound of the first band gap; (c) Mode C at the lower bound of the second band gap; (d) Mode D at the upper bound of the second band gap.

Fig. 8. Band gap edge evolution with the change of the tuning parameter *δ*. The exchange in the first two wave mode branches induces band inversion and accidental degeneracy at $\delta = 0$. In particular, the first band gap is non-trivial since it closes and re-opens, while the second one is trivial.

Fig. 9. Eigen-modes of the unit cell for different *δ*. The left column corresponds to the results of the case with *δ* = − 0.5, and the right column corresponds to *δ* = 0.5. (a)-(h) correspond to the locations P_2 , P_2 ', P_1 , P_1 ', S_2 , S_2 ', S_1 and S_1 ' labeled in Fig. 8, respectively. From top to bottom, their corresponding frequencies are 922.06 Hz, 1179.9 Hz, 1786.1 Hz and 2152.0 Hz, respectively.

Fig. 10. Schematic of the topological sandwich meta-structure. (a) Isometric view; (b) Top view. The structure is still composed of substrate plates and hourglass lattices, but the unit cells in the left and right sides of the interface are mirror symmetric. Besides, the hourglass lattices are of the same size as the preceding metastructure, and the total unit cells are consistent with the original design.

$$
\begin{bmatrix} \mathbf{S}_{e} & \mathbf{S}_{ef} \\ \mathbf{S}_{ef}^{T} & \mathbf{S}_{f} \end{bmatrix} \begin{bmatrix} \mathbf{d}_{e} \\ \mathbf{d}_{f} \end{bmatrix} = \begin{bmatrix} \mathbf{r}_{e} \\ \mathbf{r}_{f} \end{bmatrix} + \begin{bmatrix} \mathbf{f}_{e} \\ \mathbf{f}_{f} \end{bmatrix},
$$
(47)

where **d, r**, and **f** are the vectors of displacement, reaction forces, and external forces, respectively. The subscripts e and f are short for "essential'' and "free'', respectively. Since the reaction force at the free nodes is equal to zero, we have $\mathbf{r}_f = \mathbf{0}$. Besides, there is no external load at the given nodes, i.e. $f_e = 0$. Hence, Eq. (47) is rewritten as

$$
\begin{bmatrix} \mathbf{S}_{\rm e} & \mathbf{S}_{\rm ef} \\ \mathbf{S}_{\rm ef}^{\rm T} & \mathbf{S}_{\rm f} \end{bmatrix} \begin{bmatrix} \mathbf{d}_{\rm e} \\ \mathbf{d}_{\rm f} \end{bmatrix} = \begin{bmatrix} \mathbf{r}_{\rm e} \\ \mathbf{f}_{\rm f} \end{bmatrix} . \tag{48}
$$

The unknown variables can be solved as

$$
\begin{cases} \mathbf{d}_{\mathrm{f}} = \mathbf{S}_{\mathrm{f}}^{-1} \left(\mathbf{f}_{\mathrm{f}} - \mathbf{S}_{\mathrm{ef}}^{\mathrm{T}} \mathbf{d}_{\mathrm{e}} \right) \\ \mathbf{r}_{\mathrm{e}} = \mathbf{S}_{\mathrm{e}} \mathbf{d}_{\mathrm{e}} + \mathbf{S}_{\mathrm{ef}} \mathbf{S}_{\mathrm{f}}^{-1} \left(\mathbf{f}_{\mathrm{f}} - \mathbf{S}_{\mathrm{ef}}^{\mathrm{T}} \mathbf{d}_{\mathrm{e}} \right) \end{cases} \tag{49}
$$

In view of $f_f = 0$, we have

$$
\begin{cases} \mathbf{d}_{\mathrm{f}} = -\mathbf{S}_{\mathrm{f}}^{-1} \mathbf{S}_{\mathrm{ef}}^{\mathrm{T}} \mathbf{d}_{\mathrm{c}} \\ \mathbf{r}_{\mathrm{e}} = \left(\mathbf{S}_{\mathrm{e}} - \mathbf{S}_{\mathrm{ef}} \mathbf{S}_{\mathrm{f}}^{-1} \mathbf{S}_{\mathrm{ef}}^{\mathrm{T}} \right) \mathbf{d}_{\mathrm{e}} \end{cases} \tag{50}
$$

As a common practice, it is assumed that the left (clamped) end of the meta-structure is imposed with the harmonic excitation, and the vibration amplitude of the right (free) end is the output quantity of interest. Therefore, the transmittance is expressed as

$$
\psi(\omega) = 20\log(d_{out}/d_{in}),\tag{51}
$$

where the displacements of the input and output ends can be extracted from the solution of Eq. (49) . By definition, the vibration is attenuated if $\psi(\omega) < 1$.

The band gap width is one of the core indicators to characterize the vibration attenuation ability. To quantitatively evaluate the band gap width of different meta-structures, a central-frequency normalized band gap width Δ*G* that avoids frequency dependence is defined as [[58,59](#page-16-0)]:

$$
\Delta G = \frac{2(f_u - f_l)}{f_u + f_l},\tag{52}
$$

where f_u and f_l are the lower and upper bound frequencies of the band gap.

3. Finite element verification

This section presents a corresponding FE model for verifying the

Fig. 11. Transmittances of the topological meta-structure calculated by SEM and FEM. The transmittance of the ordinary meta-structure (dash-dot line) is also provided for reference and comparison. Compared to the ordinary sandwich meta-structure, a solitary peak appears in the first band gap-induced vibration suppression valley of the topological meta-structure.

Fig. 12. Comparison of the vibration modes of the designed topological meta-structure at different frequencies: (a) 854 Hz, (b) 1022 Hz, (c) 1158 Hz, (d) 1982 Hz, and (e) 2106 Hz. (b) corresponds to the vibration mode of the topological interface state. In (b), the center of the meta-structure, where is the topological interface, exhibits the maximum vibration.

developed theoretical model in Section 2. Both the band structure and the transmittance response of the sandwich meta-structure will be demonstrated.

Without loss of generality, a sandwich meta-structure consisting of 12 unit cells along the *x*-direction is considered in the verification case study. The structural parameters of the meta-structure are listed in [Table 1.](#page-5-0) The substrate plates and hourglass lattices are made of steel with material parameters listed in [Table 2.](#page-6-0)

The transmittances of the proposed meta-structure are calculated by both SEM and FEM. The FE model is built using the commercial software COMSOL Multiphysics®. To take account of the damping effect, a complex elastic modulus E_c is adopted, i.e., $E_c = E_0(1 + i\eta)$, where η is the intrinsic loss factor of the material. [Fig. 5](#page-6-0) compares the results from the developed SEM model and the FE simulation. It can be clearly seen that the transmittance response computed by SEM agrees well with that acquired from the conventional FEM: two band gaps exist over the frequency ranges of 907–1194 Hz and 1735–2240 Hz. According to the definition, the normalized band gap widths are $\Delta G_1 = 0.273$ and $\Delta G_2 =$ 0.254, respectively. Compared with the metamaterials proposed in [\[60](#page-16-0), [61\]](#page-16-0), the present meta-structure produces two wider band gaps at the low-frequency ranges.

Furthermore, the band structure is analyzed to understand potential wave types in the sandwich meta-structure. As depicted in the righthand side subplots of [Fig. 6](#page-7-0), modes I and II stand for the longitudinal vibration modes in the substrate plates and hourglass lattices in the *x* and *y* directions, respectively. Modes III and V indicate the torsional wave propagation in the meta-structure. Modes IV and VI are the symmetric transverse modes. The branches corresponding to these modes are colored in gray since they will be triggered only under specific excitation conditions. Given the excitation condition applied in this study, only the asymmetric transverse modes in the blue-colored branches can be activated. We annotate them as AT mode in the figure for brevity. In terms of the AT mode wave propagation in the proposed meta-structure, two complete band gaps highlighted in the cyan area of [Fig. 6](#page-7-0) are opened. A narrower one appears in the lower frequency ranges, and a wider one forms in the higher frequency range. The two band gaps are, respectively, over the frequency range of 907–1194 Hz and 1735–2240 Hz. The band gap ranges are consistent

Fig. 13. Spatial distribution of the dimensionless displacement amplitude along the length of the topological meta-structure. For the interface mode, the maximum vibration concentrates at the junction interface and decays away from there.

Fig. 14. Diagram of the positions and sizes of the introduced defects to the topological sandwich meta-structure. The defects are all circle-shaped with a radius of 1 cm. The defects are introduced to the top plates and situated at the middle of the corresponding subcell.

with the transmittance analysis results in [Fig. 5](#page-6-0).

In accordance with previous works $[21,62]$ $[21,62]$ $[21,62]$, the normalized frequency $f_n = f c/v_s$ is introduced to non-dimensionalize the result. Here, *c* and $v_s = [E/(2\rho(1+\mu))]^{1/2}$ denote the lattice constant and shear wave velocity, respectively. Accordingly, the shear wave velocity in the uniform steel material is 3130.354 m/s. After normalization, the two band gap ranges are non-dimensionalized to be 0.058–0.076 and 0.111–0.143, respectively. The results suggest that the lattice constant of the proposed meta-structure is much smaller than the wavelength, indicating a remarkable ability to suppress low-frequency vibration.

Next, we will elaborate on whether the LR or BS mechanism induces the band gaps. As shown in [Fig. 5,](#page-6-0) the attenuation property varies smoothly over the two band gap ranges, which is the typical behavior of a BS band gap [\[63\]](#page-16-0). In contrast, in a typical LR band gap region, a sharp maximum attenuation occurs at a certain frequency, and the transmittance profile over this region is usually asymmetric. For a sandwich metamaterial beam with LR band gaps, one can refer to [\[64\]](#page-16-0) to compare its transmittance profile and will notice an evident sharp spike on the transmittance curve in its band gap region. In addition, the eigenmode shapes corresponding to the lower and upper bound modes (labeled in [Fig. 6](#page-7-0)) of the two band gaps are plotted in [Fig. 7](#page-8-0) to help identify the type of band gaps. It can be found that all four eigenmode shapes do not exhibit any local resonance phenomenon. The trusses in different cells are in the same thermal color as the substrate plate at the same location in the identical cell. In other words, all trusses carry out in-phase motion with the substrate plates. In the case of a typical LR band gap, its upper and lower bound modes should exhibit energy localization in the local

resonators, and the local resonators should show out-of-phase vibration with the host structure [\[65,66](#page-16-0)]. The above analyses confirm that the band gaps in [Figs. 5](#page-6-0) and [6](#page-7-0) belong to BS band gaps.

4. Topological sandwich meta-structure

In this section, a topological sandwich meta-structure is designed. The formation mechanism of the topological interface state is explained, and the related dynamic characteristics are discussed in detail based on the developed theoretical model.

4.1. Band inversion

The topological state formation is usually accompanied by the band inversion phenomenon. By maintaining the substrate plates untouched, we aim to adjust the design of the core lattice to induce band inversion in the proposed meta-structure. A tuning parameter δ is first introduced:

$$
\delta = \frac{2(r_2 - r_1)}{r_1 + r_2} \tag{53}
$$

Note that the radii of the rods are controlled to satisfy $r_1+r_2 = 4$ mm. By varying δ and tracking the band gap bounds, [Fig. 8](#page-8-0) shows the evolution of the band edges. It can be found that the first band gap closes and reopens as δ increases from negative to positive. Along with the degeneration of two eigenmodes, the band inversion for the first band gap occurs at $\delta = 0$, i.e., the up and down positions of the blue and red branches are swapped. However, the band inversion does not show up in

Fig. 15. Transmittances of the topological sandwich meta-structures with and without defects. The topological interface state never disappears and always locates around 1022 Hz.

Fig. 16. Spatial distribution of the dimensionless displacement amplitude along the topological meta-structures with and without defects. Even if defects exist, the maximum vibration always concentrates at the junction interface.

Fig. 17. Transmittances of the topological sandwich meta-structures with different damping loss factors. The band gaps are of similar characteristics, and the topological interface state is always triggered around 1022 Hz.

the second band gap, which indicates that the second band gap does not support the formation of any topological interface state.

4.2. Polarization transition

The band inversion indicates that the wave modes at the edges of the band gap will be exchanged. By setting δ to -0.5 and 0.5, the wave modes at the edges of the two band gaps are presented and compared in [Fig. 9.](#page-8-0) It is noted that the wave modes at the upper edge of the second band gap, i.e., P2 [\(Fig. 9](#page-8-0)(a)) and P2' [\(Fig. 9\(](#page-8-0)b)), are similar. Also, the wave modes at the lower edge of the second band gap, i.e., P1 ([Fig. 9\(](#page-8-0)c)) and P1' [\(Fig. 9](#page-8-0)(d)), are analogous. This signifies that the wave modes at the edges of the second band gap remain almost the same after changing the sign of *δ*, which is as predicted by the edge evolution result shown in [Fig. 8](#page-8-0). Therefore, we can confirm that topological interface states will never occur in the second band gap. Unlike the second band gap, by comparing [Fig. 9\(](#page-8-0)e) and (h), we find that the vibration mode at the upper/lower edge of the first band gap is flipped to the lower/upper edge if the sign of *δ* is changed. The modal polarization transition is further confirmed if we examine and compare the vibration modes in Fig. $9(g)$ and (f). This modal polarization transition phenomenon

provides a good sign for the appearance of the topological interface state in the first band gap.

It is worth noting that calculating the topological invariants, such as the Zak phase for one-dimensional cases, can help identify the topological transition. However, the geometry of the sandwich structure studied in this paper is complicated. Therefore, calculating the Zak phase is not an easy task. Fortunately, researchers have proposed a discretized form to obtain approximated Zak phases [\[67](#page-16-0),[68\]](#page-16-0). Based on the theoretical model developed in this paper and by referring to the discretized form in [[67,68\]](#page-16-0), it could be possible to calculate the Zak phase numerically. Still, there are some challenges in implementing the numerical calculation. Therefore, this needs further effort and could be prospective work.

4.3. Interface mode formation

Based on the understanding of the polarization transition behavior, a topological sandwich meta-structure, as shown in [Fig. 10](#page-9-0), is constructed by assembling two finite chains in different topologies. Each of the leftand right-hand side chains consists of 6 cells. The tuning parameter *δ* of the unit cells in the left-hand side chain is set to − 0.5, and that for the

Fig. 18. Effect of damping loss factor on the energy distribution. Different damping loss factors do not change the energy localization position of the topological interface mode.

right-hand side chain is set to 0.5. For comparison, an ordinary metastructure with a uniform topology along the assembled cells, i.e., the tuning parameter δ of all the unit cells are maintained the same, is also constructed. The band structure and transmittance results of the ordinary meta-structure have already been presented in [Figs. 5](#page-6-0) and [6](#page-7-0).

By adopting the SEM approach elucidated in [Section 2,](#page-2-0) we can also calculate the transmittance of the proposed topological meta-structure. Except for the tuning parameter δ , the other geometric and material parameters are the same as listed in [Tables 1](#page-5-0) and [2](#page-6-0). The corresponding result is presented in [Fig. 11](#page-9-0). The FEM result is also provided for reference. As expected and already verified in the case study in [Section](#page-9-0) [3](#page-9-0), the SEM result agrees well with the FEM result: the blue dash line tightly overlaps with the solid red curve. For the topological metastructure, two wide band gaps are generated, respectively, in the frequency ranges of 861–1149 Hz and 1742–2282 Hz. The centralfrequency normalized band gap widths are $\Delta G_1 = 0.286$ and $\Delta G_2 =$ 0.269, respectively. Compared with the ordinary meta-structure, the band gap widths are not influenced too much after introducing the topological design concept. The most noticeable phenomenon in the topological meta-structure is the occurrence of the solitary peak in the first band gap-induced vibration attenuation valley on the transmittance curve. This newly appeared solitary peak at 1022 Hz signifies the formation of the topological interface state.

On the transmittance curve, the topological interface state exhibits a peak just like other normal resonant peaks, except it is solitarily situated in the band gap-induced vibration attenuation valley. For this reason, the topological interface state is not easily distinguishable by barely examining the transmittance response. To further reveal and also confirm the feature of a topological interface state, one can plot out its vibration mode. The result is presented in [Fig. 12](#page-10-0). To make a high contrast comparison, the vibration modes at the nearby resonant peaks and several peaks in or at the edge of the second band gap-induced attenuation valley are also presented. For the normal peaks, their vibration modes as shown in Fig. $12(a)$ and (c)-(e) are pretty arbitrary and share no common feature. For the vibration mode of the topological interface state, as shown in Fig. $12(b)$, it is observed that the transverse motion of the meta-structure concentrates at the middle position, which is the intentionally designed topological interface. As the topological interface state is formed at a frequency in the band gap, the transverse motions at other places of the meta-structure are much smaller and decay exponentially from the middle interface. Though the topological meta-structure proposed in the article is achieved based on a sandwich beam, the vibration mode of its topological interface state shares a

similar feature as those reported in the existing literature [[36,37](#page-15-0)[,69](#page-16-0)].

4.4. Energy localization

The vibration mode shown in [Fig. 12](#page-10-0)(b) suggests that the topological interface state has an energy localization ability. As the kinetic energy in a vibration system is amplitude-dependent, we can quantify the energy distribution by the displacement amplitude field along the length of the sandwich meta-structure. [Fig. 13](#page-10-0) depicts the dimensionless displacement amplitude distribution along the length of the topological metastructure. Note that the displacement here refers to the relative displacement to the base; thus, the dimensionless displacement amplitude at 0 equals 0, indicating that the base excitation is applied from the left end of the topological meta-structure. It is distinctly shown that the maximum amplitude occurs when the dimensionless length equals 0.5, i. e., at the center of the meta-structure. Though the excitation is input from the left end, and the right end is not constrained under the free condition, the maximum energy is predestined to concentrate at the interface between the two chains with different topologies. This predetermined behavior might be helpful and have valuable potential in structural health monitoring for the ease of characteristic information collection and energy harvesting for boosting energy conversion efficiency.

4.5. Effect of geometry defects on the localization ability

It is well-known that topological interface states are robust against defects and imperfections [\[10\]](#page-15-0). In the following, we intentionally introduce some defects and investigate their effects on the energy localization ability of the topological interface state. As shown in [Fig. 14](#page-11-0), the defects are introduced by drilling circular holes in the top plates of the sandwich meta-structure. The radius of the circular holes is 1 cm. The center of each circular hole locates at the middle of the corresponding subcell. We explored five cases. The first four cases only have a single defect hole at the subcell numbered 10, 12, 14, and 16, respectively. The last case has four defect holes at the positions mentioned above.

The transmittances of the defected topological sandwich metastructures are shown in [Fig. 15](#page-11-0). The transmittance of the intact (no defect) topological sandwich meta-structure is also plotted out for reference. It can be observed that the introduction of defects did not make the interface state disappear. The peak amplitudes are not significantly affected. In addition, regardless of the defect position, the topological interface state always forms around 1022 Hz.

The displacement distributions along the meta-structures with defects are examined to confirm that the topological sandwich metastructure did not lose the energy localization ability even if manufacturing-caused defects and imperfections exist. As demonstrated in [Fig. 16,](#page-12-0) the maximum vibration invariably concentrates at the junction interface. Compared with the intact topological sandwich metastructure, the energy decay speed from the junction interface of the defected ones may decrease. We have further explored more cases by drilling defect holes elsewhere. The results are not presented but are very similar, and the energy localization abilities of the defected topological sandwich meta-structures are undoubtedly confirmed. This indicates that the defects may slightly deteriorate the energy localization ability but will not make it disappear entirely.

4.6. Effect of damping loss factor on the interface mode

Since the sandwich meta-structure is made of aluminum, the range of the damping loss factor η is 0.0001–0.02 [\[12\].](#page-15-0) Through a comparative study of the frequency responses for different *η*, the effect of material loss factor on interface modes is revealed in [Fig. 17.](#page-12-0) Although the transmission efficiency fluctuates with the change of damping, the band gap characteristics of the sandwich meta-structure are not affected by the material loss factor *η*. Moreover, the topological interface state never disappears and always locates around 1022 Hz.

In addition, we have also evaluated the effect of damping loss factor on the interface mode via the energy localization phenomenon. As shown in [Fig. 18,](#page-13-0) for the sandwich meta-structure, the energy attenuation rate around the interface will reduce with the increase of damping. However, the maximum displacement amplitudes always emerge at the junction interface, indicating the robustness of the energy localization ability possessed by the topological interface mode. As demonstrated above, it can be concluded that the material damping could affect the energy distribution of the topological interface mode but could not easily take away the energy localization ability from the sandwich metastructure.

5. Conclusions

 \overline{a}

This article has presented a study of constructing topological interface states in hourglass lattice sandwich meta-structures. Unlike simple structures analyzed in previous studies, hourglass lattice sandwich metastructures have much more complicated geometries, posing a great challenge for their theoretical modeling and topological design. We first developed an analytical approach for modeling such sandwich metastructures based on the extension of the spectral element method (SEM). A corresponding finite element (FE) model has verified the

analytical model. We designed a tuning parameter to trigger and induce the topological change in sandwich meta-structures. The tuning parameter was defined as the dimensionless radius difference between struts in two adjacent lattices. We then investigated the topological change of the sandwich meta-structure by varying the tuning parameter. The band inversion and polarization transition analyses indicated that the first band gap supports the generation of topological interface states while the second band does not. Based on the above results, we designed a topological sandwich meta-structure. The transmittance analysis revealed the occurrence of a solitary peak in the first band gap-induced vibration attenuation valley due to the introduction of the topological design strategy. The vibration mode at the solitary peak exhibited the typical behavior of a topological interface state, i.e., the transverse motion of the meta-structure concentrated at the junction interface and the kinetic energy localized there.

In summary, this work has provided insights into the possibility of endowing hourglass lattice sandwich meta-structures with topological properties. It has also developed a general theoretical framework for formulating the analytical models for analogous meta-structures. Since this work focuses on establishing the theoretical formulation of such sandwich systems, the investigation of the back-scattering immune phenomenon that requires extending the current model to a 2D structure with acute-angled waveguides will be conducted in further work.

Appendix A. Explicit expression of four coefficient matrices in [Eq. \(35\)](#page-5-0)

For the sake of description, we define the following variables

$$
\begin{cases}\n\varpi_1 = \mu \beta_{jn}^2 - q_{jn1}^2, & \varpi_2 = \mu \beta_{jn}^2 - q_{jn2}^2, & \varpi_3 = \mu \alpha_{km}^2 - p_{km1}^2, \\
\varpi_4 = \mu \alpha_{km}^2 - p_{km2}^2, & \varpi_5 = \mu \alpha_{km}^2 + \beta_{jn}^2, & \varpi_6 = \alpha_{km}^2 + \mu \beta_{jn}^2, \\
\varpi_7 = 2(-1)^{m+n} / \left[\sqrt{\zeta_{km} \zeta_{jn} ab} \left(p_{km1}^2 + \beta_{jn}^2 \right) \left(p_{km2}^2 + \beta_{jn}^2 \right) \right], \\
\varpi_8 = 2(-1)^{m+n} / \left[\sqrt{\zeta_{km} \zeta_{jn} ab} \left(q_{jn1}^2 + \alpha_{km}^2 \right) \left(q_{jn2}^2 + \alpha_{km}^2 \right) \right], \\
\varpi_9 = (1 - \mu)^2 \alpha_{km}^2 \beta_{jn}^2 + \rho h \mu \omega^2 / D, & \tau_0 = \sqrt{4 \rho h \omega^2 / D}, \\
\tau_1 = H_k (q_{jn1} a) / H_k^* (q_{jn1} a), & \tau_2 = H_k (q_{jn2} a) / H_k^* (q_{jn2} a), \\
\tau_3 = H_j (p_{km1} b) / H_k^* (p_{km1} b), & \tau_4 = H_j (p_{km2} b) / H_k^* (p_{km2} b).\n\end{cases}
$$
